

Course Name: Cloud Computing

ASSESSMENT TOOL - 1

1.

2.(A)

(B)

3.

4. The concept map, technical matrices, and cloud-flow diagram demonstrate CO1 by showing how cloud computing concepts are applied in the project. The project uses appropriate service models such as PaaS for application hosting, DBaaS for database management, and Object Storage for file storage. REST APIs enable secure communication between the frontend, backend, and cloud services. Elasticity allows resources to automatically adjust based on workload, while scalability supports increasing users and data without affecting performance. The compute layer uses virtualization or managed cloud services to improve resource utilization and reduce infrastructure management. Finally, the shared responsibility model clearly defines that the cloud provider manages infrastructure, security, and availability, while the student application team manages the application code, data, APIs, and user access. This demonstrates an understanding of cloud architecture and its practical implementation in the project.
